Methodology statement: Vintage 2025 Esri Time Series Totals

Introduction Esri's Vintage Time Series Totals database contains data for total population, households, and housing units for every year between Census 2010 and Esri's current estimates. This data is available for all 27 geographic schemas included in Esri Updated Demographics down to the smallest level, Uber H3 hexagons—level 7. For 2025, the Time Series covers the time period from 2010 to 2025. This database provides users with valuable insight, looking back 16 years to evaluate trends and patterns in current geography.

Data sources and model Esri's Time Series estimates are released annually alongside the current-year estimates of total population, households, and housing units. With each annual release, the entire Time Series is revised from July 1, 2010, through July 1 of the year prior to the current release of Esri's Updated Demographics. The revised Time Series estimates fill the void between Census 2010 and Updated Demographics, providing a historical view from the 2010 census year to the current year. As the estimates for all years are revised each year, the Time Series estimates are referred to by their vintage, using the current year to denote the vintage of the Time Series estimates. Therefore, the Vintage 2025 Time Series includes estimates for July 1, 2010, through July 1, 2025.

The decennial census is a snapshot of the population on April 1 every 10 years. Esri's Time Series begins with a July 1, 2010, point estimate. This July 1 estimate includes corrections made to the census counts by Esri over the past decade, from 2010 to 2019. Typical census errors include missed housing units, demolished housing, housing units counted where there are none, and group quarters that were misclassified or counted in the wrong location.

The July 1, 2011, to July 1, 2019, estimates of total population, households, and housing units represent Esri's existing postcensal estimates that have been converted to current 2020-based geography and smoothed to match the 2010 to 2020 endpoints. These 2011 to 2019 estimates distribute the difference between Esri's 2020 postcensal estimate and Esri's Census 2020 realigned count, or error of closure, to all years in the 2011 to 2019 time series using multiple algorithms. The end product is a time series consisting of intercensal estimates within the two decennial census endpoints.

The 2020 year of the time series represents Esri's July 1, Census 2020 realigned data and is not a replication of the official April 1, 2020, decennial count. Esri's realigned Census 2020 base includes adjustments to more than 500 block groups to rectify inconsistencies caused by the Census Bureau's new data privacy methods.¹ The July 1, 2020, estimate not only improves Esri census counts but also allows for a uniform year-over-year data series based on a standard point in time. Census 2020 privacy methods have introduced impossible or improbable statistics, such as cases

¹ [Esri Realigns Census 2020 Data for Esri Updated Demographics](#) blog article.

of households but no household population or exceptionally high average persons per household. Esri provides fixes for these errors and omissions whenever possible to ensure that the Time Series database has a solid and stable base to build on.

Estimates from 2021 to 2025 represent Esri postcensal estimates that have been smoothed to account for routine data fluctuations and backfilled with new data and corrections whenever possible. 2025 estimates are an exact match with 2025 Esri Updated Demographics estimates.

Demographic change has traditionally been measured by comparing the previous decennial census to estimates from the current year of Esri Updated Demographics. Prior to the release of Time Series estimates, changes such as methodological improvements and the integration of new source data precluded comparison of estimates from the current year to previous years. With Time Series estimates, every attempt is made to build a consistent temporal dataset that can be used to evaluate year-over-year change. Model inputs are backfilled when possible, and erratic change has been dampened throughout the database. In many cases in which modeling proved consistent, the Time Series estimates will be unchanged from Esri's annual release of Updated Demographics.

Standard statistical and political geography changes are made throughout the decade. To conduct meaningful and accurate analysis, geographic areas must be stable. Time Series estimates use the most recent geographic boundaries for all years of data. Vintage 2025 Esri Time Series Totals include geographic, name, and code changes for Connecticut's nine new county-equivalent boundaries. This is particularly valuable for geographies that change on a regular basis, such as ZIP codes, places, congressional districts, and core-based statistical areas.

Esri, the global market leader in geographic information system (GIS) software, location intelligence, and mapping, helps customers unlock the full potential of data to improve operational and business results.

Founded in 1969 in Redlands, California, USA, Esri software is deployed in more than 350,000 organizations globally and in over 200,000 institutions in the Americas, Asia and the Pacific, Europe, Africa, and the Middle East. Esri has partners and local distributors in over 100 countries on six continents, including Fortune 500 companies, government agencies, nonprofits, and universities. With its pioneering commitment to geospatial information technology, Esri engineers the most innovative solutions for digital transformation, the Internet of Things (IoT), and advanced analytics.
